Preface

Purpose

The purpose of the EPTS glossary of terms is to facilitate industry use of event processing technology by providing a common language for developing applications and software infrastructure that use event processing concepts.

The event processing glossary has three goals:

- Accelerate the learning of the event processing concept
- Further community communication by enabling practitioners to utilize common concepts and terms
- Provide a foundation for analysis and the development of best practices, publications, and industry standards

Organization

The glossary is presented according to the logical order of the terms. An index with an alphabetical listing is available at the beginning of the document for convenience.

Content

This glossary covers a small set of basic terms related to event processing. It will be frequently periodically updated with additional terms in response to suggestions from the event processing community for improvements and additions.

Our approach is to define each term independently of any particular implementation, product, or domain of application. So, for example, the term event object has popular meanings as a tuple, a vector, a row, etc. These are all realizations of events in particular approaches and products. Even the most basic term, event, is problematic. Essentially there are two distinct meanings:

An activity that happens

Something that represents that activity in a computer system

It is tempting to introduce two separate terms such as event and event object. However, in any discussion longer than a paragraph or two, this becomes intolerably clumsy and one finds the distinction being misused, forgotten or dropped altogether. For example, using the two separate terms would dictate that —event processing (see below) should be —event object processing. The best solution is to overload the word —event. The context of each use becomes the indicator of which meaning is intended. This has been standard practice in the field of event-driven simulation for the past thirty years. It was the approach taken by the physicists of the early 20th century in discussions of relativity where —event also has two meanings. We have chosen to follow their example in the knowledge that it did not lead them into ambiguity problems.

Alphabetical Index of Glossary Terms

Cause
Clock
Complex event
Complex event processing (CEP)
Composite event
Constraint (event pattern constraint)
Derived event (synthesized event, synthetic event)
Event
Event (event object, event message, event tuple)
Event abstraction
Event attribute (event property)
Event channel
Event cloud
Event consumer ~~sink~~ (event sink, event handler, event listener)
Event driven
Event-driven architecture (EDA)
Event management
Event pattern
Event pattern detection
Event pattern discovery
Event pattern triggered reactive rule
Event processing
Event processing agent (EPA) (event processing component, event mediator)
Event processing language (EPL)
Event processing network (EPN)
Event producer (event source, event emitter)
Event stream
Event stream processing (ESP)
Event template
Event timing
Event type (event class, event definition, event schema)
Instantaneous event
Pattern instance (event pattern instance)
Publish-and-subscribe
Publisher
Raw event
Relationships between events
Rule (in event processing)
Simple event
Subscriber
Time interval
Timestamp
Virtual event
Window (in event processing)

Glossary of Terms

Event

Anything that happens, or is contemplated as happening.

Examples:

- A financial trade
- An airplane lands
- A sensor outputs a reading
- A change of state in a database or a finite state machine
- A key stroke
- A natural occurrence such as an earthquake
- A social or historical happening, e.g., the abolition of slavery, the battle of Waterloo, the Russian Revolution, and the Irish potato famine.

Event (event object, event message, event tuple)

An object that represents, encodes, or records an event, generally for the purpose of computer processing.

Examples:

- A purchase order (records a purchase activity)
- An email confirmation of an airline reservation
- Stock tick message that reports a stock trade
- A message that reports an RFID sensor reading
- A medical insurance claim document

Notes:

1. Events are processed by computer systems by processing their representations as event objects. The same activity may be represented by more than one event object; each event object might record different attributes of the activity. In many event processing systems, for example simulation systems, events are immutable. In such systems, a modification or transformation of an event must be achieved by creating a new event object and not by altering the original event. Deletion would entail removing an event from further processing.
2. Overloading: Event objects contain data. The word —event is overloaded so that it can be used as a synonym for event object. In discussing event processing, the word —event is used to denote both the everyday meaning (anything that happens) and the computer science meaning (an event object or message). The context of each use indicates which meaning is intended.

Virtual event

An event that does not happen in the physical world but is imagined, modeled or simulated.

Examples:

- Instruction executions modeled by a hardware design simulation
- Events predicted by a weather simulation
- Events modeled by a war game
- Events that take place in a dream (“these dreams of you, so real and so true” — Van Morrison)
- Events in virtual reality

Note: A virtual event can refer to either an event object or a thing that happens.

Event type (event class, event definition, or event schema)

A class of event objects.

Examples:

- The type of all price quotations
- The type of all sensor readings for any kind of sensor

Notes:

1. All events must be instances of an event type. An event has the structure defined by its type. The structure is represented as a collection of event attributes (below).
2. Event types should be defined within the type definition system of a modern strongly typed computer language such as XML Schema or Java. Any standard for representing events will usually specify certain predefined data (attributes), examples of which might be:
 - A unique event identifier used to reference the event
 - The type of the event
 - The time stamps of the event’s creation
 - The source of creation for the event

Event attribute (event property)

A component of the structure of an event.

Note: An event attribute can have a simple or complex data type.

Event processing

Computing that performs operations on events, including reading, creating, transforming, or discarding events.

Note: The overloaded meaning event object processing is intended in this context.

Clock

A process that creates an ordered ascending sequence of values of type Time with a uniform interval between them.

Note: Each value is produced at a tick (or clock tick). The length of the interval between clock ticks is called a chronon (the clock's granularity).

Event timing (timing)

The time value attributes of an event.

Timestamp

A time value attribute of an event recording the reading of a clock in the system in which the event was created or observed.

Examples:

- Creation time: the time interval or time at which an event was created
- Arrival time: the time at which an event arrived at a point of observation

Notes:

1. An event can contain timestamps according to one or more clocks. For example, it can contain both its creation time according to a clock where it was created and its arrival time at a system location according to a clock at that location.
2. In systems with multiple clocks, the issue of clock synchronization is an ongoing topic of research. Not all timing attributes are timestamps. Timing in derived events, for example, may be derived from timing of the source events.

Time interval

A period of time bounded by two timing attributes called the interval's start time and end time.

Instantaneous event

An event that happens at a point in time.

Note: If they are recorded, the start and end times of an instantaneous event are the same.

Cause

An event A is a cause of another event B, if A had to happen in order for B to happen.

Examples:

- The birth of a father and the birth of a son of the father;
- Sending an email and a reply to that email

Note: This is a definition of computational causality. It requires A to be necessary for B to happen. For example B's father is a cause of B, but so is B's mother. Other definitions of causality are possible, e.g., probable cause. The meaning and definitions of intentional or philosophical causality have been debated in countless books on philosophy.

Complex event

An event that summarizes, represents, or denotes a set of other events.

Examples:

- The 1929 stock market crash – an abstraction denoting many thousands of member events, including individual stock trades)
- The 2004 Indonesian Tsunami – an abstraction of many natural events
- A CPU instruction –an abstraction of register transfer level (RTL) events
- A completed stock purchase –an abstraction of the events in a transaction to purchase the stock
- A successful on-line shopping cart checkout – an abstraction of shopping cart events on an on-line website

Notes:

1. A complex event can be an event object or anything that happens, depending on the context.
2. All derived events are complex, but not all complex events are derived from event objects (they may arise from other sources).
3. An event that is regarded as complex in one application might be viewed as a simple event in another application.
4. A complex event can convey additional information that was not present in any of the events that gave rise to it.

Event abstraction

The relationship between a complex event and the other events that it denotes, summarizes, or otherwise represents.

Note: This definition applies to the use of abstraction in an event processing context. The term abstraction is used elsewhere in computer science in other ways.

Derived event (synthesized event, synthetic event)

An event that is generated as a result of applying a method or process to one or more other events.

Examples:

- An event reporting that company B has entered the bidding to take over A with probability 0.9, might be derived from an event reporting that the price of company A's stock has jumped 10% in 5 minutes.
- The absence of an event, say in a given time interval, can lead to a derived event reporting that the first event did not happen.

Notes:

1. A derived event is an event object.
2. A derived event is a kind of complex event, although not all complex events are derived.

Composite event

A derived event that is created by combining a set of other simple or complex events (known as its members) using a specific set of event constructors such as disjunction, conjunction, and sequence. A composite event always includes the member (base) events from which it is derived.

Notes:

1. A composite event is an event object – something that happens cannot be a composite event.
2. A composite event is a kind of complex event.
3. A derived event is not a composite if its method of derivation lies outside a specified set of allowed constructors.
4. The terminology “composite” and “constructor” originated in the field of Active Database research.

Relationships between events

Events are related by time, causality, abstraction, and other relationships. Time and causality impose partial orderings upon events.

Notes:

1. Regarding the relationships of composite, derived and complex events: A composite event or a derived event is a complex event. The converses are not necessarily true.

2. The term aggregate event is sometimes used for some forms of composite or derived event.

Simple event

An event that is not viewed as summarizing, representing, or denoting a set of other events.

Notes:

1. All events are either simple or complex. Simple event is the complement to complex event.
2. Simple and complex are relative terms. A simple event to one observer may be complex to another.

Raw event

An event object that records a real-world event.

Note: A raw event may represent a simple real-world event (e.g., the phone rang) or a complex real-world event. For example, the stock market crash of 1929 was a complex real world event that can be recorded by a complex raw event.

Event hierarchy

A model that represents the relationships between events that are at different levels of abstraction with respect to each other.

Note: A complex event is usually at a higher level in the hierarchy than the events that it denotes, summarizes, or otherwise represents.

Complex event processing (CEP)

Computing that performs operations on complex events, including reading, creating, transforming, abstracting, or discarding them.

Note: CEP ultimately creates complex events even if some or all of the source events are simple events. See also the definitions for event stream processing (ESP), event streams, and event clouds, below.

Event producer (event source, event emitter)

An event processing agent that sends events.

Examples:

- Software module

- Sensor
- Clock

Event consumer (event sink, event handler, event listener)

An event processing agent that receives events

Examples:

- Software module
- Database
- Dashboard

Event channel

Any means of conveying event objects.

Notes:

1. A channel can carry events of multiple types.
2. Events transported by a single channel may be consumed by multiple event consumers (the channel is said to fan out).
3. Events transported by a single channel may originate in multiple producers and be delivered to one consumer (the channel is said to fan in).

Event template

An event form or descriptor, some of whose parameters are variables. An event template matches single events by replacing the variables with values.

Examples:

- Send of any message
- String Msg; Send(John, Msg)

Event pattern

A template containing event templates, relational operators and variables. An event pattern can match sets of related events by replacing variables with values.

Examples:

- A pattern of events defining those sets of events in a completed sales transaction
- A pattern of events in an email correspondence: String Msg, Time T1, T2 ; Send(John, Msg, T1) and Receive(John, Msg, T2)
- A pattern defining the events in any successfully resolved customer complaint: Customer C, Agent A, Problem P, Time T1, T2, T3; Complain(C, P, T1) → Engage(A, C, T2) → Resolved (P, T3)

Note: Event patterns can often be specified graphically.

Pattern instance (event pattern instance)

A set of related events resulting from an event pattern where the variables are replaced by values.

Example:

Send (John, See the NYT today, 15.00 EST) and Receive(John, See the NYT today, 12.05 PST).

Constraint (event pattern constraint)

A Boolean condition that must be satisfied by the events observed in a system.

Example:

A service level agreement limiting the time taken to complete a mortgage transaction from the time an application is received.

Event pattern discovery

Finding new event patterns.

Event pattern detection

Finding instances of an event pattern.

Notes:

1. The process of deciding whether a set of events is an instance of a pattern is called matching.
2. Discovery deals with finding new patterns, whereas detection deals with matching a given pattern.

Rule (in event processing)

A prescribed method for processing events.

Examples:

- Whenever three timeouts have happened, send an alert to the network manager.
- If more than ten shopping carts have been active for more than five minutes, then activate the website reaction time monitor and display an amber alert on the dashboard.
- Whenever IBM trades 2% above its 1 hour VWAP and then within 15 minutes trades 5 points below, then buy 1000 shares IBM.

Note: Event processing rules may be prescribed in many different ways, including by finite state machines, UML diagrams, graphical methods, Java code, SQL code, ECA (event-condition-action) rules or reactive rules that are triggered by event patterns (below).

Event pattern triggered reactive rule

A rule that prescribes actions to be taken whenever an instance of a given event pattern is detected.

Event processing agent (EPA) (event processing component, event mediator)

An entity that processes event objects.

Notes:

1. An EPA may perform different kinds of computation on events such as filtering, aggregating, and detecting patterns of events.
2. An EPA can be recursive – it can be an EPN consisting of multiple EPAs and channels.
3. Event source and event sink are roles that an EPA may play. An EPA could act in both roles - it could be an event producer at one moment and an event consumer at another time.

Event processing language (EPL)

A high level computer language for defining the behavior of event processing agents.

Event management

An IT discipline that encompasses event governance, event policy management, and the design, development, testing, deployment, maintenance, and administration of events, event models, event metadata, and related aspects of systems that process events.

Event stream

A linearly ordered sequence of events.

Notes:

1. Usually, streams are ordered by time, e.g., arrival time;
2. An event stream may be bounded by a certain time interval or other criteria (content, space, source), or be open ended and unbounded.
3. A stream may contain events of many different types.

Window (in event processing)

A bounded segment of an event stream.

Example:

The events in the last ten minutes – i.e., a ten-minute moving window.

Note: Windows define subsequences of an event stream typically to focus the event processing on specific data or to improve event processing performance; however, they may also have other uses.

Event stream processing (ESP)

Computing on inputs that are event streams.

Example:

Applications that use stock market feeds as inputs and process events in their order of arrival to compute running average stock prices, volume weighted average prices over time windows, etc.

Notes:

1. ESP has its origins in active databases and data streams management;
2. The terms ESP and CEP are conceptual classifications. They can be useful in delineating philosophies of event processing and intended applications, but do not specify precisely the underlying capabilities of event processing engines.

Event cloud

A partially ordered set of events (poset), either bounded or unbounded, where the partial orderings are imposed by the causal, timing and other relationships between the events.

Notes:

1. Typically an event cloud is created by the events produced by one or more distributed systems.
2. An event cloud may contain many event types, event streams, and event channels.
3. The difference between a cloud and a stream is that there is no event relationship that totally orders the events in a cloud. A stream is a cloud, but the converse is not necessarily true.
4. CEP usually refers to event processing that assumes an event cloud as input, and therefore can make no assumptions about the arrival order of events.

Event Processing Network (EPN)

A set of event processing agents (EPAs) and the channels they use to communicate.

Notes:

1. The runtime deployment of an event processing network may be distributed across multiple physical networks, computers, and software artifacts.
2. An EPN can be an EPA, i.e., EPAs and EPNs can be recursive.

Publish-and-subscribe (pub-sub)

A method of communication in which messages are delivered according to subscriptions.

Notes:

1. Subscriptions define which messages should flow to which consumers.
2. Event processing applications may use publish-and-subscribe communication for delivering events. However, publish-and-subscribe is not definitional to event processing – other communication styles may be used.

Publisher

An agent that sends events that are disseminated by a publish-and-subscribe protocol.

Subscriber

An agent that submits a subscription for publish-and-subscribe communication.

Note: In most publish-and-subscribe systems, the consumer must be the subscriber. However, in some systems, the subscriber can be a third party.

Event driven

The behavior of a device, software module or other entity whose execution is in response to the arrival of events from external or internal sources.

Examples:

- A cell phone
- An event triggered rule
- An operating system

- A bank's trust department where the personnel spend their time putting out fires (i.e., event-driven rather than goal-driven or directed)

Event-driven architecture (EDA)

An architectural style in which components are event driven and communicate by means of events.

Notes:

1. Architecture is the fundamental organization of a system embodied in its components, their relationships to each other and to the environment, and the principles guiding its design and evolution (from IEEE).

2. An architectural style is a coordinated set of architectural constraints that restricts the roles/features of architectural elements and the allowed relationships among those elements within any architecture that conforms to that style (from Roy T. Fielding).

Glossary According to Lexicographic Order (definitions only)

Cause: An event A is a cause of another event B if A had to happen in order for B to happen.

Clock: A process that creates an ordered ascending sequence of values of type Time with a uniform interval between them.

Complex event: An event that summarizes, represents, or denotes a set of other events.

Complex-event processing (CEP): Computing that performs operations on complex events, including reading, creating, transforming, abstracting, or discarding them.

Composite event: A derived event that is created by combining a set of other simple or complex events (known as its members)-using a specific set of event constructors such as disjunction, conjunction, and sequence. A composite event always includes the member (base) events from which it is derived.

Constraint (event pattern constraint): A Boolean condition that must be satisfied by the events observed in a system.

Derived event (synthesized event, synthetic event): An event that is generated as a result of applying a method or process to one or more other events.

Event: Anything that happens, or is contemplated as happening.

Event (event object, event message, event tuple): An object that represents encodes or records an event, generally for the purpose of computer processing.

Event abstraction: The relationship between a complex event and the other events that it denotes, summarizes, or otherwise represents.

Event attribute (event property): A component of the structure of an event.

Event channel: Any means of conveying event objects.

Event cloud: A partially ordered set of events (poset), either bounded or unbounded.

Event consumer (event sink): An event processing agent that receives events.

Event driven: The behavior of a device, software module or other entity whose execution is in response to the arrival of events from external or internal sources.

Event-driven architecture (EDA): An architectural style in which components are event driven and communicate by means of events.

Event hierarchy: A model that represents the relationships between events that are at different levels of abstraction with respect to each other.

Event management: An IT discipline that encompasses event governance, event policy management, and the design, development, testing, deployment, maintenance, and administration of events, event models, event metadata, and related aspects of systems that process events.

Event pattern: A template containing event templates, relational operators and variables. An event pattern can match sets of related events by replacing variables with values.

Event pattern detection: Finding instances of an event pattern.

Event pattern discovery: Finding new event patterns.

Event pattern triggered reactive rule: A rule that prescribes actions to be taken whenever an instance of a given event pattern is detected.

Event processing: Computing that performs operations on events, including reading, creating, transforming, or discarding events

Event processing agent (EPA) (event processing component, event mediator): A software module that processes events.

Event processing language (EPL): A high level computer language for defining the behavior of event processing agents.

Event processing network (EPN): A set of event processing agents (EPAs) and a set of event channels connecting them.

Event producer (event source, event emitter): An event processing agent that sends events.

Event stream: A linearly ordered sequence of events.

Event stream processing (ESP): Computing on inputs that are event streams.

Event template: An event form or descriptor some of whose parameters are variables. An event template matches single events by replacing the variables with values.

Event timing: The time value attributes of an event.

Event type (event class, event definition, or event schema): A class of event objects.

Instantaneous event: An event that happens at a point in time.

Pattern instance (event pattern instance): A set of related events resulting from an event pattern by replacing the variables by values.

Publish-and-subscribe: A method of communication in which messages are delivered according to subscriptions.

Publisher: An agent that sends events that are disseminated by a publish-and-subscribe protocol.

Raw event: An event object that records a real-world event.

Relationships between events: Events are related by time, causality, abstraction and other relationships. Time and causality impose partial orderings upon events.

Rule (in event processing): A prescribed method for processing events.

Simple event: An event that is not viewed as summarizing, representing, or denoting a set of other events.

Subscriber: An agent that submits a subscription for publish-and-subscribe communication.

Time interval: A period of time bounded by two timing attributes called the interval's start time and end time.

Timestamp: A time value attribute of an event recording the reading of a clock in the system in which the event was created or observed.

Virtual event: An event that does not happen in the physical world but is imagined, modeled, or simulated.

Window (in event processing): A bounded segment of an event stream.

Acknowledgements We are indebted to many correspondents who have made contributions, suggestions and comments over the past year. They are too numerous to mention individually, but we owe them our thanks.
